## Lecture 14: Object Oriented Programming and Classes

# About These Slides

- Based on Chapter 18 of the book  
*An Introduction to Programming Through C++*  
by Abhiram Ranade (Tata McGraw Hill, 2014)
- Original slides by Abhiram Ranade
  - First update by Varsha Apte
  - Second update by Uday Khedker

# Main Recommendations From The Previous Chapter

- Define a `struct` to hold information related to each entity that your program deals with
- Define member functions corresponding to actions/operations associated with the entity

# Outline

- Constructors
- Copy Constructors
- Destructors
- Operator overloading
- Overloading the assignment operator
- Access control
- Classes
- Graphics and input/output classes

# Motivational Example: The Queue Struct in Taxi Dispatch

```
const int N=100;
struct queue{
    int elements[N],
        nwaiting,front;
    bool insert(int v){
        ...
    }
    bool remove(int &v){
        ...
    }
};
```

- Once the queue is created, we expect it to be used only through the member functions, insert and remove
- We do not expect elements, nWaiting, front to be directly accessed

# Main Program Using Queue

```
int main(){
    Queue q;
    q.front = q.nWaiting = 0;
    while(true){
        char c; cin >> c;
        if(c == 'd'){
            int driver; cin >> driver;
            if(!q.insert(driver))
                cout <<"Q is full\n";
        }
        else if(c == 'c'){
            int driver;
            if(!q.remove(driver))
                cout <<"No taxi.\n";
            else cout <<"Assigning <<
                driver<< endl;
        }
    }
}
```

- Main program does use q through operations insert and remove
- However, at the beginning, q.front and q.nWaiting is directly manipulated
- This is against the philosophy of software packaging
- When we create a queue, we will always set q.nWaiting and q.front to 0
- C++ provides a way by which the initialization can be made to happen automatically, and also such that programs using Queue do not need to access the data members directly
- Just defining Queue q; would by itself set q.nWaiting and q.front to 0!

— Next

# Constructor Example

- In C++, the programmer may define a special member function called a **constructor** which will always be called when an instance of the struct is created
- A constructor has the same name as the struct, and no return type
- The code inside the constructor can perform initializations of members
- When q is created in the main program, the constructor is called automatically

```
struct Queue{  
    int elements[N], front,  
        nWaiting;  
    Queue(){ // constructor  
        nWaiting = 0;  
        front = 0;  
    }  
    // other member functions  
};  
  
int main(){  
    Queue q;  
    // no need to set  
    // q.nWaiting, q.front  
    // to 0.  
}
```

# Constructors In General

```
struct A{  
    ...  
    A(parameters){  
        ...  
    }  
};  
  
int main(){  
    A a(arguments);  
}
```

- Constructor can take arguments
- The creation of the object **a** in main can be thought of as happening in two steps
  - Memory is allocated for **a** in main
  - The constructor is called on **a** with the given arguments
- You can have many constructors, provided they have different signatures

## Another example: Constructor for V3

```
struct V3{  
    double x,y,z;  
    V3(){  
        x = y = z = 0;  
    }  
    V3(double a){  
        x = y = z = a;  
    }  
};  
int main();  
    V3 v1(5), v2;  
}
```

- When defining **v1**, an argument is given
- So **the constructor taking a single argument** is called. Thus each component of v1 is set to 5
- When defining v2, no argument is given. So **the constructor taking no arguments** gets called. Thus each component of v2 is set to 0

# Remarks

- If and only if you do not define a constructor, will C++ defines a constructor for you which takes no arguments, and does nothing
  - If you define a constructor taking arguments, you implicitly tell C++ that you want programmers to give arguments. So if some programmer does not give arguments, C++ will flag it as an error
  - If you want both kinds of initialization, define both kinds of constructor
- A constructor that does not take arguments (defined by you or by C++) is called a default constructor
- If you define an array of struct, each element is initialized using the default constructor

# The Copy Constructor

- Suppose an object is passed by value to a function
  - It must be copied to the variable denoted by the parameter
- Suppose an object is returned by a function
  - The value returned must be copied to a temporary variable in the calling program
- By default the copying operations are implemented by copying each member of one object to the corresponding member of the other object
  - You can change this default behaviour by defining a copy constructor

# Example

```
struct Queue{  
    int elements[N], nWaiting, front;  
    Queue(const Queue &source){ // Copy constructor  
        front = source.front;  
        nWaiting = source.nWaiting;  
        for(int i=front, j=0; j<nWaiting; j++){  
            elements[i] = source.elements[i];  
            i = (i+1) % N;  
        }  
    };  
};
```

# Copy Constructor in the Example

- The copy constructor must take a single reference argument: the object which is to be copied
- Note that the argument to the copy constructor must be a reference, otherwise the copy constructor will have to be called to copy the argument! This will result in an unending recursion
- Member elements is not copied fully. Only the useful part of it is copied
  - More efficient
- More interesting use later

# Destructors

- When control goes out of a block in which a variable is defined, that variable is destroyed
  - Memory allocated for that variable is reclaimed
- You may define a destructor function, which will get executed before the memory is reclaimed

# Destructor Example

- If a queue that you have defined goes out of scope, it will be destroyed
- If the queue contains elements at the time of destruction, it is likely an error
- So you may want to print a message warning the user
- It is usually an error to call the destructor explicitly. It will be called automatically when an object is to be destroyed. It should not get called twice.
- More interesting uses of the destructor will be considered in later chapters.

# Destructor Example

```
struct Queue{  
    int elements[N], nWaiting, front;  
    ...  
    ~Queue(){    //Destructor  
        if(nWaiting>0) cout << "Warning:"  
            <<" non-empty queue being destroyed."  
            << endl;  
        }  
};
```

# Operator Overloading

- In Mathematics, arithmetic operators are used with numbers, but also other objects such as vectors
- Something like this is also possible in C++!
- An expression such as `x @ y` where `@` is any “infix” operator is considered by C++ to be equivalent to `x.operator@(y)` in which `operator@` is a member function
- If the member function `operator@` is defined, then that is called to execute `x @ y`

## Example: Arithmetic on V3 objects

```
struct V3{  
    double x, y, z;  
    V3(double a, double b, double c){  
        x=a; y=b; z=c;  
    }  
    V3 operator+(V3 b){           // adding two V3s  
        return V3(x+b.x, y+b.y, z+b.z); // constructor call  
    }  
    V3 operator*(double f){       // multiplying a V3 by f  
        return V3(x*f, y*f, z*f); // constructor call  
    }  
};
```

# Using V3 Arithmetic

```
int main(){  
  
    V3 u(1,2,3), a(4,5,6), s;  
  
    double t=10;  
  
    s = u*t + a*t*t*0.5;  
  
    cout << s.x << ' ' << s.y << ' '  
        << s.z << endl;  
  
}
```

## Remarks

- Expression involving vectors can be made to look very much like what you studied in Physics
- Other operators can also be overloaded, including unary operators (see the book)
- Overload operators only if they have a natural interpretation for the struct in question
- Otherwise you will confuse the reader of your program

# The `this` pointer

- So far, we have not provided a way to refer to the receiver itself inside the definition of a member function.
- Within the body of a member function, the keyword `this` points to the receiver i.e. the struct on which the member function has been invoked.
- Trivial use: write `this->member` instead of `member` directly.

```
struct V3{  
    double x, y, z;  
    double length(){  
        return sqrt(*this.x * *this.x  
                    + *this.y * *this.y  
                    + *this.z * *this.z);  
    }  
}
```

- More interesting use later.

# Overloading The Assignment Operator

- Normally if you assign one struct to another, each member of the rhs is copied to the corresponding member of the lhs
- You can change this behaviour by defining member function `operator=` for the struct
- A return type must be defined if you wish to allow chained assignments, i.e. `v1 = v2 = v3`; which means `v1 = (v2 = v3)`;
  - The operation must return a reference to the left hand side object

# Example

```
struct Queue{
    ...
    Queue & operator=(Queue &rhs){
        front = rhs.front;
        nWaiting = rhs.nWaiting;
        for(int i=0; i<nWaiting; i++){
            elements[i] = rhs.elements[i];
            i = (i+1) % N;
        }
        return *this;
    }
};
// only the relevant elements are copied
```

# Access Control

- It is possible to restrict access to members or member functions of a struct
- Members declared public: no restriction
- Members declared private: Can be accessed only inside the definition of the struct
- Typical strategy: Declare all data members to be private, and some subset of function members to be public

# Access Control Example

```
struct Queue{  
private:  
    int elements[N], nWaiting, front;  
public:  
    Queue(){ ... }  
    bool insert(int v){  
        ..  
    }  
    bool remove(int &v){  
        ..  
    }  
};
```

# Remarks

- **public**, **private** : access specifiers
- An access specifier applies to all members defined following it, until another specifier is given
- Thus elements, nWaiting, front are private, while Queue(), insert, remove are public

## Remarks

- The default versions of the constructor, copy constructor, destructor, assignment operator are public
- If you specify any of these as private, then they cannot be invoked outside of the struct definition
- Thus if you make the copy constructor of a struct X private, then you will get an error if you try to pass a struct of type X by value
- Thus, as a designer of a struct, you can exercise great control over how the struct gets used

# Classes

- A class is essentially the same as a struct, except:
  - Any members/member functions in a struct are public by default
  - Any members/member functions in a class are private by default

# Classes

- Example: a Queue class:

```
class Queue{  
    int elements[N], nWaiting, front;  
public:  
    Queue(){...}  
    bool remove(int &v){...}  
    bool insert(int v){...}  
};
```

- Members elements, nWaiting and front will be private.

# Example

```
struct V3{  
    double x,y,z;  
    V3(double v){  
        x = y = z = v;  
    }  
    double X(){  
        return x;  
    }  
};
```

```
struct V3{  
    double x,y,z;  
    V3(double v);  
    double X();  
};  
//implementations  
V3::V3(double v){  
    x = y = z = v;  
}  
double V3::X(){  
    return x;  
}
```

# Input Output Classes

- `cin`, `cout` : objects of class `istream`, `ostream` resp. predefined in C++
- `<<`, `>>` : operators defined for the objects of these classes
- `ifstream`: another class like `istream`
- You create an object of class `ifstream` and associate it with a `file` on your computer
- Now you can read from that file by invoking the `>>` operator!
- `ofstream`: a class like `ostream`, to be used for writing to files
- Must include header file `<fstream>` to use `ifstream` and `ofstream`

## Example of file i/o

```
#include <fstream>
#include <simplecpp>
int main(){
    ifstream infile("f1.txt");
    // constructor call. object infile is created and associated
    // with f1.txt, which must be present in the current directory
    ofstream outfile("f2.txt");
    // constructor call. Object outfile is created and associated
    // with f2.txt, which will get created in the current directory
```

## Example of file i/o

```
repeat(10){  
  int v;  
  infile >> v;  
  outfile << v;  
}
```

```
// f1.txt must begin with 10 numbers. These will be read and  
// written to file f2.txt
```

```
}
```

# Concluding Remarks

- The notion of a packaged software component is important.
- Making data members private: hiding the implementation from the user
- Making some member functions public: providing an **interface** using which the object can be used
- Separation of the concerns of the developer and the user
- Idea similar to what we discussed in connection with ordinary functions
  - The specification of the function must be clearly written down (analogous to **interface**)
  - The user should not worry about how the function does its work (analogous to hiding data members)
